Abstract. We show that if no m -plane contains almost all of an m -rectifiable set $E \subset \mathbf{R}^n$, then there exists a single $(m-1)$ -plane V such that the radial projection of E has positive m -dimensional measure from every point outside V .

1. Introduction

The purpose of this note is to investigate the relation between rectifiability and *radial projections* $\pi_x: \mathbf{R}^n \setminus \{x\} \rightarrow \mathbf{S}^{n-1}$, $x \in \mathbf{R}^n$, defined by the expression $\pi_x(y) = (y-x)/|y-x|$. Motivated by the famous result of Besicovitch and Federer concerning orthogonal projections (see [Mat95, Theorem 18.1]), one has reason to anticipate that the radial projections $\pi_x(E)$ of m -rectifiable sets $E \subset \mathbf{R}^n$ with $\mathcal{H}^m(E) > 0$ ought to have positive \mathcal{H}^m measure for almost all parameters $x \in \mathbf{R}^n$, whereas the opposite behaviour should be manifest in the purely unrectifiable case. The problem of verifying this intuition in the unrectifiable case appears to be rather involved, and only partial results are available (see the discussion and references in section 5); this note complements those results by settling the rectifiable case. We show that if no m -plane contains almost all of an m -rectifiable set $E \subset \mathbf{R}^n$ with $\mathcal{H}^m(E) > 0$, then \mathcal{H}^m almost all radial projections of E have positive m -dimensional measure. We also provide an accurate 'worst case' description of the geometry of the *exceptional set* $\{x \in \mathbf{R}^n: \mathcal{H}^m(\pi_x(E)) = 0\}$. Our studies were initiated by a question on 'directions of rectifiable sets', raised by Iosevich, Mourougolou and Senger in the recent preprint [IMS10]: a positive answer to this question is acquired in Remark 4.1.

2. Preliminaries and the main result

An \mathcal{H}^m measurable set $E \subset \mathbf{R}^n$ with $\mathcal{H}^m(E) > 0$ is called *m -rectifiable* if there are countably many C^1 -embeddings $f_i: \mathbf{R}^m \rightarrow \mathbf{R}^n$ such that

$$\mathcal{H}^m\left(E \setminus \bigcup_i f_i(\mathbf{R}^m)\right) = 0.$$

This definition is equivalent to the classical definition of rectifiability, where we consider coverings by Lipschitz-images instead of C^1 -manifolds, see [Mat95, Theorem 15.21]. We include the requirement $\mathcal{H}^m(E) > 0$ in the definition of rectifiability merely to avoid repetition.

We say that a set $E \subset \mathbf{R}^n$ is *m-flat*, if there exists an m -plane T such that $E \subset T$. Relaxing this condition slightly, we say that E is *essentially m-flat*, if $\mathcal{H}^m(E \setminus T) = 0$. Our main result is the following.

Theorem 2.1. *Let $E \subset \mathbf{R}^n$ be an m -rectifiable set, which is not essentially m -flat. Then $\mathcal{H}^m(\pi_x(E)) > 0$ for \mathcal{H}^m almost every $x \in \mathbf{R}^n$.¹ Moreover, the exceptional set is always $(m - 1)$ -flat.*

A 0-plane is, by definition, a singleton in \mathbf{R}^n . Note that the result fails for any essentially flat set $E \subset \mathbf{R}^n$. Indeed, if E essentially m -flat, then we may find an m -plane T such that $\mathcal{H}^m(E \setminus T) = 0$. Write

$$\pi_x(E) = \pi_x(E \setminus T) \cup \pi_x(E \cap T), \quad x \in \mathbf{R}^n.$$

The first set on the right is \mathcal{H}^m null, since $\mathcal{H}^m(E \setminus T) = 0$. For every $x \in T$, the second one is a subset of an $(m - 1)$ -sphere. Hence $\mathcal{H}^m(\pi_x(E)) = 0$ for every $x \in T$.

Furthermore, the exceptional set can be an $(m - 1)$ -plane. For this just take any two m -planes T_1 and T_2 such that $T_1 \neq T_2$ but $V := T_1 \cap T_2$ is non-empty. Now V is an $(m - 1)$ -plane. Define $E := T_1 \cup T_2$. Then, for every $x \in V$, the radial projection $\pi_x(E)$ consists of two $(m - 1)$ -spheres. Hence, $\mathcal{H}^m(\pi_x(E)) = 0$ for every $x \in V$.

3. The key lemma

The main result is a consequence of the following lemma, which concerns the local bilipschitz-properties of the radial projection.

Lemma 3.1. *Let $f: \mathbf{R}^m \rightarrow \mathbf{R}^n$ be a C^1 -embedding, and let $z_0 = f(\mathbf{x}_0)$ be a point such that $\dim f'(\mathbf{x}_0)\mathbf{R}^m = m$. Then, if $x \notin T := z_0 + f'(\mathbf{x}_0)\mathbf{R}^m$, there exists $\delta > 0$ such that $\pi_x|_{f(\mathbf{R}^m) \cap B(z_0, \delta)}$ is bilipschitz.*

Proof. We may and will assume that $z_0 = 0$. Write $M := f(\mathbf{R}^m)$, and fix $y = f(\mathbf{y}), z = f(\mathbf{z}) \in M$. Since f is differentiable at \mathbf{z} , say, we have

$$\begin{aligned} y - z &= f(\mathbf{y}) - f(\mathbf{z}) = f'(\mathbf{z})(\mathbf{y} - \mathbf{z}) + \varepsilon(\mathbf{y} - \mathbf{z})|\mathbf{y} - \mathbf{z}| \\ &= f'(\mathbf{x}_0)(\mathbf{y} - \mathbf{z}) + [f'(\mathbf{z}) - f'(\mathbf{x}_0)](\mathbf{y} - \mathbf{z}) + \varepsilon(\mathbf{y} - \mathbf{z})|\mathbf{y} - \mathbf{z}|, \end{aligned}$$

where $\varepsilon: \mathbf{R}^m \rightarrow \mathbf{R}^n$ is, as usual, some function with the property that $\varepsilon(h) \rightarrow 0$ as $h \rightarrow 0$ in \mathbf{R}^m . Denote the three vectors on the previous line by t, e_1 and e_2 . Since $\dim f'(\mathbf{x}_0)\mathbf{R}^m = m$, we have the inequality $|t| \geq c|\mathbf{y} - \mathbf{z}|$ for some $c > 0$. On the other hand, choosing $y = f(\mathbf{y})$ and $z = f(\mathbf{z})$ close to $z_0 = 0$ ensures that \mathbf{y} and \mathbf{z} are close to \mathbf{x}_0 , since f is an embedding. It follows that

$$|e_1| \leq \varepsilon|\mathbf{y} - \mathbf{z}| \quad \text{and} \quad |e_2| \leq \varepsilon|\mathbf{y} - \mathbf{z}|,$$

as soon as $y, z \in B(0, \delta) \cap M$. Above $\varepsilon > 0$ can be made arbitrarily small by taking $\delta > 0$ small. Here we also needed the fact that f is continuously differentiable. Denote by P_T the orthogonal projection onto $T = f'(\mathbf{x}_0)\mathbf{R}^m$. Since $t \in T$, we may

¹Note that $\pi_x(E)$ is not, strictly speaking, well defined, if $x \in E$. Here, and in the rest of the paper, the notation $\pi_x(E)$ should be interpreted as $\pi_x(E \setminus \{x\})$.

Hence π_x restricted to $B(0, \delta) \cap M$ is bilipschitz. □

4. Proof of the main result

Proof of Theorem 2.1. Choose a C^1 -embedding $f_1: \mathbf{R}^m \rightarrow \mathbf{R}^n$ so that $M_1 := f_1(\mathbf{R}^m)$ intersects E in a set of positive \mathcal{H}^m measure. Next choose a point $z_1 = f_1(\mathbf{x}_1) \in E \cap M_1$ such that $\dim f'_1(\mathbf{x}_1)\mathbf{R}^m = m$ and z_1 is a density point of $E \cap M_1$. All this is possible by Sard's theorem and the fact that \mathcal{H}^m almost every point of $E \cap M_1$ is a density point. Write $T_1 := z_1 + f'_1(\mathbf{x}_1)\mathbf{R}^m$. By our assumption, $\mathcal{H}^m(E \setminus T_1) > 0$. Now repeat the previous procedure: choose a C^1 -embedding $f_2: \mathbf{R}^m \rightarrow \mathbf{R}^n$ such that $M_2 := f_2(\mathbf{R}^m)$ intersects $E \setminus T_1$ in a set of positive \mathcal{H}^m measure. Also, pick a point $z_2 = f_2(\mathbf{x}_2) \in (E \setminus T_1) \cap M_2$ such that, again, $\dim f'_2(\mathbf{x}_2)\mathbf{R}^m = m$ and z_2 is a density point of $(E \setminus T_1) \cap M_2$. Set $T_2 := z_2 + f'_2(\mathbf{x}_2)\mathbf{R}^m$. Then $T_1 \neq T_2$.

Let $x \in \mathbf{R}^n$. If $x \notin T_1$. Then, by Lemma 3.1, there exists $\delta > 0$ such that $\pi_x|_{M_1 \cap B(z_1, \delta)}$ is bilipschitz. Since $E \cap M_1 \cap B(z_1, \delta)$ has positive \mathcal{H}^m measure, so does $\pi_x(E \cap M_1 \cap B(z_1, \delta))$. Similarly, if $x \notin T_2$, we find $\delta > 0$ such that $\pi_x([E \setminus T_1] \cap M_2 \cap B(z_2, \delta))$ has positive \mathcal{H}^m measure. This implies that the set of all $x \in \mathbf{R}^n$ with $\mathcal{H}^m(\pi_x(E)) = 0$ is necessarily a subset of $T_1 \cap T_2$, which is always contained in an $(m - 1)$ -plane. □

Remark 4.1. In [IMS10, Conjecture 1.12], Iosevich et al. asked the following: *if E is $(n - 1)$ -rectifiable and not $(n - 1)$ -flat, then does the set of directions*

$$\mathcal{D}(E) := \left\{ \frac{y - x}{|y - x|} : y, x \in E, y \neq x \right\}$$

always have positive \mathcal{H}^{n-1} measure? Lemma 3.1 implies a positive answer: one may even replace $n - 1$ by any integer $0 < m < n$. In fact, slightly more is true: if $E \subset \mathbf{R}^n$ is an m -rectifiable set, which is not m -flat, then there exists $x \in E$ such that $\mathcal{H}^m(\pi_x(E)) > 0$. The proof of this is almost the same as that of Theorem 2.1—only simpler. Choose a C^1 -embedding $f: \mathbf{R}^m \rightarrow \mathbf{R}^n$, such that $M := f(\mathbf{R}^m)$ intersects E in a set of positive \mathcal{H}^m measure. Then choose a point $z_0 = f(\mathbf{x}_0) \in E \cap M$ such that $\dim f'(\mathbf{x}_0)\mathbf{R}^m = m$ and z_0 is a density point of $E \cap M$. Write $T := z_0 + f'(\mathbf{x}_0)\mathbf{R}^m$. By our assumption $E \not\subset T$, so we may choose a point $x \in E \setminus T$. Now Lemma 3.1 yields $\delta > 0$ such that $\pi_x|_{M \cap B(z_0, \delta)}$ is bilipschitz. Since $E \cap M \cap B(z_0, \delta)$ has positive \mathcal{H}^m measure, so does $\pi_x(E \cap M \cap B(z_0, \delta))$.

5. Radial projections of unrectifiable sets

In analogue with the Besicovitch-Federer projection theorem, it seems reasonable to conjecture that the following converse for the result in this note is also true: the radial projections $\pi_x(E)$ of every purely m -unrectifiable set $E \subset \mathbf{R}^n$ are \mathcal{H}^m null for \mathcal{H}^m almost every $x \in E$. This was recently verified for self-similar sets in \mathbf{R}^2 satisfying the open set condition by Simon and Solomyak in [SiSo06]. In [Mar54, Mat81] Marstrand and Mattila also proved that $\mathcal{H}^m(\pi_x(E)) > 0$ can only happen for x in a set of dimension at most m . In the plane, at least, this upper bound cannot be improved: Marstrand exhibited an example of a purely 1-unrectifiable set $E \subset \mathbf{R}^2$, which projects radially onto a set of positive length in a set of Hausdorff-dimension exactly 1. A related phenomenon was discovered by Csörnyei and Preiss in [CsPr07]: given a purely 1-unrectifiable set $E \subset \mathbf{R}^2$ with $\mathcal{H}^1(E) < \infty$, there exists a 1-rectifiable set $F \subset \mathbf{R}^2$ with $\mathcal{H}^1(F) < \infty$ such that for \mathcal{H}^1 almost every $x \in E$ almost every line passing through x intersects F in an infinite set.
